

DEFINE PROBLEM

Problem Identification

Organizations often maintain employee information in external files such as CSV or Excel. Entering all these records manually into ServiceNow requires more time and may lead to errors.

Some common problems are:

- Manual data entry takes more time.
- Incorrect values may be entered.
- Source and target field names may be different.
- Duplicate records may be created.
- Missing information may not be identified easily.
- Large amounts of data are difficult to manage manually.

Therefore, a systematic method is required to import employee information into ServiceNow accurately.

Proposed Problem Solution

The proposed solution uses **Import Sets and Transform Maps** in ServiceNow.

The source employee data is first imported into an Import Set table. A Transform Map is then created to define the relationship between the source fields and target table fields.

After the transformation is executed, the employee records are stored in the required target table and verified.
