

PROJECT DESIGN

SOLUTION 1

Solution 1 – Source Data Preparation

The first solution focuses on preparing the employee source data before importing it into ServiceNow.

The employee data can contain fields such as:

- Employee ID
- Name
- Email
- Department
- Location

The source file should have proper column names and valid values.

Before importing, the data should be checked for:

- Missing values
- Incorrect formats
- Duplicate Employee IDs
- Incorrect email formats
- Empty mandatory fields

Proper source-data preparation helps to reduce errors during transformation.

SOLUTION 2

Solution 2 – Import Set and Transform Map

The second solution focuses on importing the source data and configuring the Transform Map.

First, the employee data file is uploaded into ServiceNow using Import Sets.

The imported information is stored in an Import Set table.

Then a Transform Map is created by selecting the required target table.

The source fields are mapped with their corresponding target fields.

Example

Source Field	Target Field
Employee ID	Employee ID
Name	Name
Email	Email
Department	Department
Location	Location

After the mapping is completed, the Transform Map is executed.

SOLUTION 3

Solution 3 – Validation and Verification

The third solution focuses on validating the transformed employee records.

After executing the Transform Map, the target table is opened and the imported records are checked.

The following points are verified:

- Employee ID is correct.
- Employee name is correct.
- Email is correctly transferred.
- Department is correctly mapped.
- Location is correctly mapped.
- No unwanted duplicate records are created.
- Import and transform results are checked.

If an error is identified, the field mapping or source data can be corrected and the transformation can be executed again.
